

PixelPainting

Design and 3D-print your own cross-stitch bookmarks — no experience needed.

iskonssss.github.io/pixelpainting

PixelPainting turns a little pixel drawing into a real, printable bookmark: a soft plastic “canvas” mesh with raised, embroidery-style **X stitches** in your colors. You draw, the app writes the printer’s instructions (a “G-code” file), and a Bambu Lab printer does the stitching. A bookmark takes about **15–30 minutes** to print and a few grams of material.

1

Open the app — make it yours

Visit the link above on your phone or computer. On a phone, tap **Share** → **Add to Home Screen** and it installs like a normal app (works offline too).

2

Start from a template

Tap  **Templates** and pick from 38 designs — flowers, hearts, night sky, rainbows... or start Blank. Everything stays editable afterwards.

3

Paint your design

Each square becomes one stitch.  **paints**,  erases,  fills an area,  picks up a color from the canvas. One finger draws; two fingers pinch to zoom. Mistake? ↩ **Undo**.

4

Choose your colors

Tap a color swatch to swap it — pick from ready-made shades or mix your own. Each color = one filament you’ll load during the print, so **2–4 colors** keeps it easy.

5

Generate & check

In  **Settings** choose **your printer model**, then tap **Generate G-code**. You’ll see a preview plus exactly **how much filament each color needs** and the print time. Tap **Download** or **Share** to save the file.

6

Print it

Copy the file onto the printer’s **SD card** (or send it over Wi-Fi with the included helper — see the website’s guide). On the printer screen: **Files** → **your file** → **Print**.

■ The printer will stop and ask for filament — that’s the magic, not a problem!

The bookmark prints in stages: first the cream canvas mesh, then the stitches, one color at a time. Before each color the printer **cuts and unloads the filament by itself**, then asks for the next one on its screen. Feed in the new color, follow the on-screen prompts (let it push material through until the new color runs clean), and the print carries on. The app tells you the color order before you start.

 **What you’ll need:** a Bambu Lab printer • PLA filament — one spool for the canvas (cream or white) plus your stitch colors • an SD card or Wi-Fi • about half an hour

You paint little squares

The printer draws each stitch

...and you get a stitched bookmark

Use PLA filament

The app’s standard settings are made for PLA — the most common, easiest material. Any brand works.

Watch the first minutes

The first layer matters most. If it’s not sticking, stop, clean the plate, and try again.

Peel gently

The mesh is thin and flexible like fabric. Wait for the bed to cool, then peel from a corner.

Nothing is lost

Designs save automatically in the app, and you can export/import them as files to share with friends.
